Java 711 Card 724 Runtine Bavironnen (ICRE) 2.1 Specification

Preface

Isvan Cardor technology combines a purion of the Isva programming language with a mutime survicumment optimized for annut cards and related, sural-monory embedded devicer. The goal of Isva Card technology is to bring tunny of the benefits of Isva Lohware programming to the resource-countrained world of annut cards.

This document is a specification of the laws Card Rentime Environment (JCRE) 2.1. A vendor of a laws Cardenabled device provides an implementation of the ICRE. A JCRE implementation within the content of this
specification refers to a vendor's implementation of the laws Card Vietnal Machine (VMI), the laws Card
Application refers to a vendor's implementation of the laws Card Vietnal Machine (VMI), the laws Card
Application. A Reference that face (API), or other component, based on the laws Card technology
specifications. A Reference that feminate in implementation produced by Sun Mivrosystems, Inc. Applets
written for the laws Card platiform are referred to as laws Card applets.

Who Should Use This Specification?

This specification is insended to assist JCRE implementer in creating an implementation, developing a specification to estend the faw Card technology specifications, or in creating an extension to the lava Card Runtime Environment (JCRE). This specification is also intended for lava Card applier developers who want a greater understanding of the Java Card technology specifications.

Before You Read This Specification

Defore reading this guide, you should be famillar with the love programming language, the lave Card textundings specifications, and struct card technology. A good resont or for boooming familiar with lave technology and lave Card technology is the Sun Nierosystems, Inc. website, technology is the Sun Nierosystems, Inc. website, technology is betp://java.eun.com

How This Specification Is Organized

Chapter t, "The Scope and Responsibilities of the JCRB," gives an overview of the services required of a JCRB impleated alian.

Chapter 2, "Lifetime of the Virtual Machine," defines the lifetime of the Virtual Machino.

Copyright @ December 14, 1998 Sun Morosystems, Inc.

5

Copyright & December 14, 1908 Sun Microsystems, Inc.

Chapter 3, "Applet Lifetime," defines the lifetime of an applet.

Clapter 4, "Trastent Objects," provides an overview of transient objects.

Chapter 3, "Sciention," describes how the ICRE handres applet sciention.

Chapter 6, "Appitet Inclation and Object Sharing," describes applie isolation and object sharing.

Chapter 7, "Transactions and Atomistipy," provides an overview of atomicity during transactions.

Chapter 8, "APP Topker," describes APP Amationality required of a ICRE but not completely specified in the Jaw Card 2.1 APP Describents.

Chapter 9, "Virtual Machine Togien," describes virtual machine specifics.

Chapter 11, "API Consteads," provides the numeric value of constants that are not specified in the Joyn Card Chapter 10, "Applet Invaller," provides an overview of the Applet Installer.

Glossery is a list of words and their definitions to axis 1 you in using fluir bock.

Java 1th Card TH Runtine Environment (JCRE) 2.1 Specification

In a PC or workstation, the Java Vinual Maddina rana sa an operating system precess. When the CS process is terninated, the Java applications and their objects are automatically destroyed.

In Java Card technology the execution lifetime of the Virtual Machine (VM) is the lifetime of the card. Most of the findmention storoid to a card shall be preserved even when power is removed from the card. Persistent menory technology (such as EEFROM) maniles a smart card to storoinformation when power is removed, solved the VMs and the objects created on the card are used to represent application information that he persistent, the Java Card VM appears to ran forever. When power is removed, the VMs stop only temperarity. When the card is rear forever, when present the same forever.

Aide from its persistent mature, the dayn Cood Virtual Mactime is just like the daya Virtual Mechine.

The card initialization thre is the time after marking, and prior to the time of eard personalization and insunner. As the time of eard judicalization, the JCRB visit library that into the formework objects extend by the JCRB visit for the lifetime of the Variet Markine and the JCRB visit in the lifetime of the Variet Markine and the JCRB controvers upon CAD beaston or the card, the lifetimes of objects created by appears will also upon CAD furners are Arcyl more Davicts, or end reader. Card tearblus are those ported when the cent is interested in the CAD, powered up, and exclauging streams of APDUs with the CAD. The card existin ends is interested in the CAD, powered up, and exclauging streams of APDUs with the CAD. The card existing ends when the card positive to the objects.

The ACRE limplementer shall make an object persistent when:

- The Applet. register muthod is culted. The ICRS states a reference to the instance of the applet object.
 The JCRS implementer shall ensure that instances of class applet are periodens.
 - A reference to an object is stored in a field of any other persistent object or in a chast's assic field. This
 requisesson at erm from the used to preserve the integrily of the ICRE's internal data structure.

Java Card Applet Lifetime ۳,

For the purposts of this specification, a Java Card apples 's lifetime begins at the point that it has boun corrently leaded unto card memory, thinked, and otherwise prepared for excountur. (For the remainder of this specification, apply refers to an applet written for the Java Casé pietform.) Applete registand with the applete, reaffector method ealst for the lifetime of the cased. The JCRE instructs with the applet vis the applet's public methods install, select, deselect, and process. An apple thal implement the scale install method. If the install method is the method is used singlemented, the applet's objects cannot be created or initialized. A JCRG insplantuation shall call to applet's install, select, describet, and process method as described below.

When the applet is installed on the smart card, the table tanta 11 method is cathed curse by the JCRE for each applet instance ercored. The JCRE shall not call the applet is exercineter directly.

The Method install 3.1

When santass is culted, no objects of the applat exist. The unstrait of the tracess i method within the applet is to create an instance of the Appl or class, and to registor the instance. All other objects that the oppict will need during its firstline can be created as is fractible. Any other preparations necessary for the applict to be selected and seccused by a CAD also can be done as in featible. The instead a medical obtains trivialization parameters from the contents of the incoming byte array parameter.

in are strongland grifes to the Argeter, regist or inclined being reflect, or if the Applet, register inclined by own exception. If the installation is ununexessial, the ICRE while perform all element when it regains Applet, reyleter unthod completes without an exception. The installation is desained unancessful if the last all inclined does not call the Applet, reglet er inchood, or if an exception is thrown from within the Typically, an applet enutra various objects, indializes them with predefined values, sets some internal state variather, and calls the Applet, ecgleter method to specify the AID (epplet Mewiliter as defined in 190 1816-5) to be used to setect it. This bisalbates is considered successful when the call to the control. That is, all persistent objects that be retinued to the state they find prior to calling the fouresta method. If the installation is successful, the ICRB can mark the applied as available for reflection.

Java 111 Card 114 Rentiture Environment (ICRE) 2.1 Specification

The Method select

Applets remain in a wapenched state until slary are explicitly selected. Selection occurs when the ICRR receives a SELECT APDU in which the name data anaethes the AID of the applet. Selection causes an applet to become the committy selected applet.

Prior to calling SELECT, the ICRE shall described the previously selected appliet. The JCRE indicates this to the applet by invaking the applet's deserbect incihod.

the ICRE informs the applied of refection by throuting its set test method.

The sypter way decline to be actoded by returning Eals of from the call to the select method or by throwing anbequent all to type roces a method, so that the applet cure tearnine the APDU countait. The applet can process the SELECT APDU command county like it processes any other APDU command. It can respond to the SELECT APDU with data (see the processe method for details), or it can flag correst by throwing an 1300-xcopt ten with the appropriate SW (retorned teature world). The SW and opdients response data are an exception. If the applied returns & time, the second SELECT APDU command is supplied to the applied in the returned to the CAD.

The Appliet..solecut invakpolet inclind shall return froe when called during the sealect method. The Appliet..solecut inched will continue to return fore during the subsequent process method, which is called to process the SELECT APPAL command.

If the applet declines to be neferted, the JCRB will return an APDU response status word of 180. SPR APPLAR. SELECT. PAREED to the CAD. Upon selection failure, the JCRE state is set to indicate that no applet is selected.

After microsofith selection, all subocquent APDUs are delivered to the currently selected applet via the process unched.

The Method process

All APDUs are received by the JCRE, which passes an initative of the APDU class to the process stackind of the community selected appliet.

Note - A SELECT APDU might cause a change in the cunrently selected applicing to the call to the process inchod.

On normal return, the JCRE automatically appeared 0x9000 as the completion responso SW to any data stready sent by the applet. At any lime during process, the applet may throw an Isobacopy Lon with an appropriate SW, in which case the KRE catches the encypian and return the SW to the CAD.

If may other exception is thrown during process, the ICRB calches the exception and returns the status word scores 6. BR_URHMPART to the CAD.

Capyright © Department 14, 1998 Sun Microsystoma, Inc. 3-5

> ÷ Copyright @ December 14, 1898 Gan Marcosystems, Inc.

7

Java 194 Card 144 Runtinus Environment (ICRE) 2.1 Specification

3,4 The Method deselect

When the JCRE receives a SELECT APDU command in which the same matches the AID of an applet, the JCRE calls the DESELECT method of the currently selected applet. This silvons the applet to perform any determine them poperations that may be required in or das to allow wene other applet to execute.

The Applet. selectingApplet mathod shall return false when called during the deselect inched. Exempions threan by the deselect method are caugh by the JCRE, but the applet is descircted.

3.5 Power Loss and Reset

Power box occurs when the eard is withdrawn from the CAD or if there is sente other mechanical or electrical failure. When power is reapplied to the card and on Card Reset (warm or only) the ICRE that conserve that:

- Transient data is recet to the default value.
- The presentation in progress, if any, when power was first (or read occurred) is abuiled.
- The applet that was referred when power was last (or read occurred) bocornes implicitly desidented. (In
 this case the denselect method is not called.)
- If the JCRE anglements default applie setection (see paragraph 5.1), the default applied is selected as the
 convenity selected appliet, and that the default appliet's selecter mellicod is called. Otherwise, the JCRE sels
 its state to indicate that no appliet is relocted.

Java 111 Card 114 Runtine Environment (JCRE) 2.1 Specification

Transient Objects 4.

Applets constitutes sequise objects that contain tempor say (transfert) dats that most not be persistent across CAD sessions. Save Cord does not support the A we knyword a rane I can. However, I save Card feetinclogy provides anchods to create francient arrays with primitive components or references to objoct.

The term "transtaut object" is a mimemen! It can be incorrectly interpreted to meen that the object itself is transfert. However, only the commun of the fields of the object (except for the brayth fields) have a frauelient mature. As with any other object to the laws programming language, transfert objects within the laws Arad platform exist as long as they are referenced from:

- The slack
- A class static field Loral variables
- A field in another existing object

A nausioni object within the lave Card platform has the following required belandor:

- The fields of a transient object shall be cheared to the field's default value (rece, false, or stult) of the occurrence of certain events (see below).
- For recurity reasons, the fields of a translets object study server be alreed in a "yersisted memory technology." Using correct stract card technology as an example, the contents of translets objects can be stored in RAM, but never in EEFROM. The purpose of this requirement is to allow translets objects to be used to store session Yeys
- Writes to the fields of a transions object shall not have a performence penelty. (Using cumous seners conditionally as an extample, the contents of transions objects can be alored in RAM, while the contents of user-transition objects can be alored in EEFROM. Typically, RAM technology has a mainh faster write cycle tine than EEPROM.)
 - aborttransaction will never cume a field in a transient object to be restired to a previous value. Weites to the fields of a unnative object shall not be afterted by "terminacious." That is, an

This beliavior unde transion objects ideal for priali amounts of remporary applied data that is frequently andified, but that need but be preserved across CAD or select sessions.

Jann 714 Card 74 Runtinse Environment (ICRE) 2.1 Specification

Events That Clear Transient Objects 4.1

transion objects are used for maintaining states that shall be preserved across applet selections, but not across card researe. CLEAR, ON, DESELECT transient objects are used for institutining states that insist be preserved while an applet is adected, but not across applet selections or card resear. Peristant objects are used for authtraning water that shall be preserved across card reacts. When a transitivit object is ereafed, one of two events are specified that canso its fields to be cleared. CLEAR, ON RESET

Details of the two circs events are as follows

- CLEAR, ON RESET—the object's fields are cleared when the card is read. When a card is porvated on, this also cause a card read.
- NOTB—It is not necessary to clear the fields of vanisms objects before ponver is removed from a card. However, it is necessary to guarantee that the previous contents of such feelds carmed be recovered ence power is lost.
- CLEAR_ON_DESELECT—the object's fields are cleared whenever any applyed is desclosted. Bocause a card sead implicitly desclosts the currently selected applet, the fields of CLEAR_ON_DESELECT objects are also cleared by the same events specified for CLEAR_ON_RESET.

The currently relaxed appliet is explicitly deselected (its deselect inwhood is called) only when a SBLECT command is processed. The currently schooled appliet is deselected and then the fields of all CLEAR_ON_DESELECT ususions to be out are cleared regardless of whether the SELECT command:

- Falls to select an applet.
 Schoots a different applet.
 Reselects the same applet.

Javs Tat Card 144 Rustine Environment (ICRE) 2.1 Specification

5. Selection

Cards receive requests for service from the CAD in the form of APDUs. The SELECT APDU is used by the ICRE to designate a currently serviced apples. Once exherted, an apples receives all subsequent APDUs until the apples becomes desetroted.

There is no correctly schotted applies when either of the following occurs:

- The card is reset and no applet has been pre-derigneted as the definal applier.
 - A SELECT commend fails when attempting to select an applet.

5.1 The Default Applet

Normally, applets become selected only via a successful SELECT command. However, some arrant cand CAD applications require that there is a default applet that is implically actooled after every card read. The behavior is:

- After card reset (or power on, which is a form of reset) the PCRE performs its initializations and chocks to see if its internal state that caches that a particular applied is the default applied. Man, the ICRE makes this applied the currently selected applied, and the applied is not not inclined in callod. If the applied is see a beet inclined throws an exception or returns to a bee, then the ICRE to its its state to indicate that no applied is addressed. (The applied is processed method is not called during default applied receive because there is an exception because there is an exception because there is an inclined to be called.
- The JCRE ensurer that the ATR has been sent and the card is now ready to accept APDU communds.

if a default applet was successfully selected, then APDU commands can be sont directly to this applet. If a default applet was not selected, then only SELECT commissible can be processed.

The mechanism for apocitying a default applet is not defined in the laws Card API 2.1. It is a JCRE implementation detail and is teft to the Individual JCRE implementation.

Jana To Card To Runtime Environment (JCRE) 2. 1 Specification

2 SELECT Command Processing

The SELECT APDU command is used to select an applet. Its behavior is:

- . The SELECT APDU is alweyn processed by the ICRE regardless of which, if any, applet is active.
- The JCRE searches its internal rable for a matching AID. The ACRE shall support adocting an applict valued the full AID is present in the SELECT command.

JCRE implementers are free to enlaure their ICRE to support eduer selection catterion. An example of this is selection was partial AID match as specified in ISO 7816-4. The specific requirements are as follows:

Note — An exteriak indicates binary bil numbering as in 18078 16. Most significant bil = b6. Leas significant bit = b1.

- Applet SELECT command was CLA=0x00, INS=0xA4.
- b) Applet SELECT command uses "Selection by DP name". Therefore, PI=DaO4
- any other value of Pt implies that is not an applet select. The APDU is processed by the currently selected applet.
- d) ICRB shall support exact DF mante (AID) artention i.e P2-3410000 ax00. (bA,b3)* are don't exic).
 - o) All other partial DF name SELECT options (b2,b1 *) are /CRB implentation dependent.

All file control information option codes (Od.k.) ahall be supported by the JCRE and interpreted may proceed by the applet.

If no AID metch is found:

H

- If there is no currently selected applet, the ICRB responds to the SELECT command with status code 0x6999 (SW_APPLET_SELECT_FAILED).
- Otherwise, the SELECT continued is forwarded to the currently selected applet's process method.
 A coatest switch into the applet's contest occurs at this point. (The applet contest is defend in purgold 6.1.1.) Applets into the SELECT APOU command for their own informal SELECT processing.
- 4. If a matching AID is found, the ACRE prepares to relect the new apple: If there is an currently referred applict, it is descited via a cell to its described method. A context reviets hat the described applict's context secure at this point. The ICRE centest is restored upon cast from descale etc.
- The JCRE art the new currently selected applet. The new applet is selected via a call to its as I each
 untilled, and a contest switch this the new applet's context occurs.
- If the applet's select inclind throws an exception or roturns fell be, then ICRE state is not so that in applet is selected. The ICRE expends to the SELECT command with status code 0x6999 (SW_APPLET_SELECT_FAILED).
- The new currently referred applied a process method is then called with the SELECT APDU as an imput parameter. A content switch into the applier's evolvent occura.

Notes -

5-2 Copyright @ December 14, 1998 Sun Microsystems, Inc.

Capright @ December 14, 1898 Sun Morosystems, Inc. 5-1

Java 111 Card 114 Runiimo Favironment (ICRE) 2.1 Specification

If there is no matching AID, the SELLICT command is forwarded to the currently selected applet (if any) for processing as a mormal applet APDI command.

if there is a matching AID and the SELECT command fails, the ICRB always enters the title where no applied is selocited.

If the unitching AID is the same as the currently arteried appter, the JCRH will goes through the process of desciousing the appter and then relecting it. Reselection could fail, leaving the card in a taste where no appted is artered.

Non-SELECT Command Processing 5.3

When a non-SELECT APDU is received and floro is no currently selected applict, the ICRE shall respond to the APDU with status code the 60099 (SW_APPLET_SELECT_FAILED).

When a non-SELECT AFDU is received and there is a currently selected applet, the JCRB invokes the process method of the currently actually packed possible as a permenter. This curres a context mylet from the JCRB context into the currently selected applet's context. When the process method exit, also why weights back to the JCRB context. The JCRB context are commented APDU and water for the cent commented APDU.

6. Applet Isolation and Object Sharing

Any implementation of the LCRE shall support inclation of contexts and applets. Inclation means that one applet can not access the fields on objects of an applet in enotive context unders the other applet explicitly provides an absence for access the fields on objects of an applet in enotion from any objects also access. The JCRE innotesolems for applet inclusion and object alsoring are detailed in the sections below.

6.1 Applet Firewall

The apply firwarll within lava Card technology is runsing-enforced protection and is aspusate from the lava technology protections. The laws language protections title apply to Java Card applets. The laws language craners that strong typing and protection altributes are enforced.

Applet firewalls are always enforced in the lava Card VM. They allow the VM to automatically perform additional security checks at materiae.

6.1.1 Contexts and Context Switching

Firevally exeminaby partition the lava Card plantorm's object system into asparate protocted object apance railed context. The firevall is the boundary between one content and another. The fCRB shall sillocate and unange an ougher context for each applied that is installed on the card. (But are paragraph & I.1.2 below for a discussion of group contexts.)

hı addiitor, the JCRE unitatins its own JCRE ramear. This context is much like an applet context, but it has special system privileges so that it can perform operations that are dealed to applet contexts.

At any point in time, there is only one native conservabilin the VM. (This is called the currently active context in order to context.) All bytecodes that access objects are checked at makine against the currently active context in order to determine if the access is allowed. A java. I and , Security exception is thrown when an access is insilenced.

When certain well-defined conditions are met diritug the execution of invoke-type bytecodes as described in paragraph 6.28, the VM per forms a content suifed. The previous content is pushed on an internal VM darch, a paragraph 6.28, the Decorace the currently active content, and the invoked method executes in this user content. Upon exit from that mathed the VM performs a restoring content switch. The original content (of the culter of the unclined) is peopled from the stack and is restored as the currently active centent. Content switches can be neared. The maximum depth depends on the ancient of VM stack space available.

Copylight @ December 14, 1998 Sun Microsystems, Inc. 6-1

Java 111 Card TM Runtime Environment (JCRE) 2.1 Specification

Most method invocations in Java Card technology do not cause a conteas switch. Ovnicat switches only occus during invocation of and return from octain methods, as well as during exception exits from those methods (see 6.2.8).

Onring a context-switching unclied invocation, an additional piece of data, indicating the currenity active centext, it pushed onto the return stack. This context is restored whan the method is exited.

Further details of contasts and context switching are provided in later sections of this chapter.

6.1.1.1 Group Contexts

Untally, each invance of a Java Card appliet defines a separate context. But with Java Card 2.1 undmodagy, the convept of green constraint is improduced. If more than one appliet is contained in a single Java package, they abore the same context. Additionally, all trustances of the same appliet dass share the tanne context. In other words, there is no friewall between two applied initiatores in a group context.

The disocusion of contexts and context twitching above in section 6.1.1 assumes that each applies instance is associated with a separate couters. In Java Card 2.1 technology, contexts are compared to enforce the forewall, and the instance AID is pushed onto the sast. Additionally, this happens was early when the context switches, but also when context switches, from an object owned by one applet instance to an object owned by another instance within the same package.

6.1.2 Object Ownership

When a new object is created, it is associated with the currently active context. But the object is owned by the applet instance within the currently active excitest when the object is instantiated. An object is owned by an applet instance, or by the ICRE.

6.1.3 Object Access

In general, an object can only be oversare! By its owning context, that it, when the owning context is the currently active context. The freewall prevents an object from being secessed by avother applet in a different context.

to implementation terms, each time on object is accessed, the object's owner content is computed to the control of these do not match, the access is not performed and a BecurityBaception in thrown.

An object is accessed when one of the following bytecodes is exounted wing the object's reformed:

qottichd, pullishd, invokevirtual, invokalnterface.
athrow, «Pralood, «Prastore, arraylength, checkcust, instanctof
«Prefettotho various hypolofaray bylocodes, tuch at balcad, sastors, etc.

This list inchudes any special or optimized frams of these bytecodes hupbaneaued in the fava Card VM, such operfield, a specified d. D. this, etc.

6.1.4 Firewall Protection

The Rays Card flewall provides protection against the most frequently unixigated security concern: developer might allow scrizified data to be "leaked" to another applet. An applet may be able to obtain an object reference from a publicly soccessible location, but if the object is contect by a different applet, the factual entures security.

Copyright @ December 14, 1998 Sun Moraeystems, Inc.

<u>5</u>

۱

Jana 144 Card Tal Runtime Environment (ICRE) 2.1 Specification

The firewall also provides protection against inscerect code. If innorrest code is leaded onto a ours, the firewall still protects objects from being accessed by this rode.

The Java Card API 2.1 specifics the basic minimum protestion requirements of contexts and firewalls because these features shall be supported in ways that are not transparent to the appler developer. Bevelopers shall be aware of the behavior of objects, APIs, and exceptions related to the firewall.

KRB implementers are free to implement additional security unchanium beyond those of the apple firewall, as levig as these nechanism are transparen to applete and do not change the externally visible operation of the VM.

Static Fields and Methods 6.1.5

ls should also de noved that classes are not owned by contexts. There is no runtime context check that can de performed when a class static field is soccased. Neither is these a context switch when a static melided is invoked. (Sindlaly, I avect capechal causes no context switch.)

Pablic static fields and gublic static melliods are accessible from any context: Maile mathods execute to the tenno context as their caller.

Objects referenced in static fields are just regular objects. They are owned by whentwer created them and standard fitterwall socks takes apply. If it is necessary to thate down arous multiple applet contents, then these objects need to be Shareably futerface Objects (SIOs). (See paragraph 6.2.4 below.)

Of course, the conventional Java technology protections are still enforced for static fields and methods. In addition, when applets are initialized, the finalities that each attempt to link to an external static field or medical paper are translation and specifical himself or the scope of this specification.

6,1.5.1 Optional static access checks

The JCRE may perform optional number checks that are redondant with the constraints enforced by a verifier. A Java (Lied Vb) may detect when code violates fundamental language restriction, such as invoking a privrite method in another class, and report or otherwise address the violation.

Object Access Across Contexts 6.2

To cuable applets to interact with each other and with the JCRE, arms well-defined yet recurs oncehanisms are provided so one constess can access an object belanging to another context.

These mechanisms are provided in the fava Cand API 2.1 and are discussed in the following sectious:

- JCRE Entry Point Objects

 - Global Arrays JCRE Privileges
- Shareduc Interfaces

Java 714 Card 714 Runtime Environment (JCRE) 2.1 Specification

JCRE Entry Point Objects 6.2.1

Scalle computor system shall have a way for inen-privileged uner processes (that are sestivited to a subset of resources) to roquest system services performed by privileged "system" routines.

In the Java Card API 2.1, this is accomplished using JCRE Eutry Poins Objects. These are objects owned by the JONE consent, but they have been flagged as containing entry point tratheds.

The firewall protects these objects from access by applear. The entry point designation allows the nuethods of these objects to be invoked from any contest. When that occurs, a contest switch to the ICRE contest is performed. These methods are the gateways through which appleas request privileged JCRE system services.

There are two categories of JCRE Entry Folm Objects:

. Temporary JCRE Entry Polus Objects

Lite all ICRE Entry Point Objecta, nuclinods of temporary JCRE Entry Point Objects can be invoked from any applet context. However, references to these objects earned be usused in class variables, instance variables or array components. The JCRE detects and restrict attempts to store references to these objects as part of the firewall functionality to prevent unauthorized re-une.

The APDII object and all ICRE oward exception objects are canapples of temporary ICRE Entry Point

Permanent JCRE Entry Point Objects

Like all KCRIE Entry Point Objects, methods of permanent ICRE Entry Point Objects can be invoked from any applet cortext. Additionally, seferences to those objects can be stored mid freely re-used.

JCRE owned AID lintances are examples of permanent ICRH Entry Point Objects

The ICRE is responsible for:

- Determining what privileged services are provided to appliets. Deferring classes containing the convy point surthands for those services.
 - Creating one or more object instances of those chates.
- Designating those Intrances as ICRE Entry Peint Objects. Designating ICRE Entry Paint Objects astemporary or permanent.
- Making references to these objects available to applets at needed.

Note — Only the method of these objects are accessible through the flowall. The fields of these objects are aill protected by the firewall and can only be accessed by the JCRE context.

Only the JCRE itself can designate Entry Point Objects and whether they are temporary or pertuanent. JCRE implements as o expossible for displementing the mechanism by which ICRE Fatry Point Objects are designated and how they become temporary or permanent.

Global Arrays

The global nature of nome objects requires that they be nexestible from any applet courtest. The frevestl would ordinarity prevent these objects from being used in a flexible manner. The Java Card VM allown an object to be designated as global. All globel ampys are temporary globel ampy objects. These objects are owned by the JCRE context, has can be necessed from any apples context. However, references to these objects cannot be stored in class sariables.

Copyright @ December 14, 1988 Sun Mccosystems, Inc. 4

Java 14 Card 194 Runtine Environment (JCRE) 2.1 Specification

inclusive variables or array components. The ANE detects and received satempts to store references to the te objects as part of the firewall functionality to prevent arranthorized resuse.

for added sexutity, only errays can be designated as global and only the JCRE taelf can designate global anays. Decause applets cannot create them, no API methods are defined. JCRE implementers are responsible for implementing the nechanism by which global arrays are designated.

At the tame of publication of this specification, the early global arrays required in the laws Card APN 2.1 are the APD() buffer and the byte array imput personates (bArray) to the applict). I nat at 1 mediced.

Note — Because of its global atabus, the APP specifics that the APDU builder in cleared to zones subserver an applet is referred, be fore the ICRE prospits a new APDU command. This is to prevent an applet is potentially tentilities data from being "leaked," to another applet via the global APDU builder. The APDU builder can be accessed from a shared mitterace edject conject and it poliable for passing data access applet ountexts. The applet is requestable for previouslike for previousling accretical and its applet in the APDU builder.

6.2.3 JCRE Privileges

Because it is the "system" content, the JCRE content has a special privilege. It can invoke a method of any object on the card. For example, assume that object X is caused by applied A. Narmally, only content A can seces the fields and methods of X. But the JCRE content is allowed to invoke any of the methods of X. During uch an invocation, a content ravited occurs from the JCRE content to the appliet content this owns X.

Note — The JCRE cut access both werhods and fields of X. Method access is the mochenism by which lie ICRE enters an applet conferent. Although the JCRE could invoke any nection through the fleverall, it shall only invoke the sale cet, processa, desail oct, and get shareautient are accepted (see 6.27.1) methods defined in the Appliet. Edst.

The JCRE content is the currently active content when the VM begins naming after a card reset. The JCRE content is the "soot" content and is always either the currently active content or the bottom content around on the stack.

6.2.4 Sharcable Interfaces

Shareable interferes are a new festure in the laws Card API 2.1 to enable applet luteraction. A shareable interfere that the case defines a set of shared interfere methods. These interfere methods can be involved from one applet context even if the abject implementing them is owned by another applet context.

In this specification, an object instance of a cleas implementing a starcable interface in eatled a Shorvebbe Interface Other (370). To the owning content, the SIO is a necrmal object whose fields and methods can be accessed. To any other exercet, the SIO is an instance of the sharesble interface, and only the methods defined in the sharesble interface, and only the methods defined in the sharesble interface are secressible. All other fields and methods of the SIO are protected by the farewall.

Shareable interfaces provide a secure involuntum for enter-apples remnunikation, as followed:

- i. To make an object available to another applet, applet A first defines a shareable interface, St. A shareable interface javacard. I reasonert. A hareable. The interfood defined in the shareable interface, St, represent the services that applet A makes accessible to other applets.
- Applet A then defines a dans Clibri implements the sharesble interface SL. C implements the unchods
 defined in SL. C may also define other methods and fields, but these are pretexted by the applet firewall.
 Only the unchods defined in SL are accessible to other applets.

Copyright @ December 14, 1990 Sun Microsystems, Inc. 6-5

Java 111 Card 114 Runtine Environment (ICRE) 2.1 Specification

- Applet A creates an object instance O of class C. Obelongs to applet A, and the firewall allows A to access
 any of the Fields and methods of O.
- To access applet A's object O, applet B creates an object reference SIO of type SI.
- Applet B invokes a special nucliod (ACByatem, get ApplatShareable interfaceObject, described in paragraph 6.2.7.2) no request a shared interface object reference from applet A.
- . Applet A receives the request and the AID of the requester (B) via Applet , qet.Shareable interfaceObject, and determines whether or took is will share edject () with applet ().
- If apple A agrees to share with apple D. A responds to the request with a reference to O. This reference is can to type Sharesbe so that now of the fields or methods of O are visible.
- 8. Applu D roceives the reject reference from applet A, carts it to type St, and stores it in object reference StO. Even though SIO sectually refer to A is object O, SIO is of type SI. Only the charache interface numbered befinned in SI are visible to B. The firewall prevents the other fields and inethods of O from being accessed by B.
- Apples B can request service from applet A by invulving one of the stratcable interface methods of S1O. During the invocation the Law Card VM performs a contest revitch. The original carroady salive contest (B) is saved on a stack and the content of the owner (A) of the actual object (O) becomes the new correctly active context. A's implementation of the charactle interface inadical (S) mailura) executes in A's context.
- 10. The SI method can find out the AID of its dirent (B) via the ACSystem, get Prav loueContext AID method. This is described in paragraph 6.2.5. The method determines whether or not it will perform the service for applet B.
- Because of the comiest switch, the firewall alloras the SI unchool to access all the fields and methods of
 object O and my other object owned by A. At the same time, the firewall provent the method from
 soccasing non-tlaned objects owned by B.
- The SI auchod con socks the parameters pareed by B and can provide a return value to B.
- During the return, the law Card VM performs a restoring content switch. The telignal corrently active content (B) is propped from the stack, and again becomes the corrent content.
- 14. Decruse of the contest switch, the furnall again allows B to access any of its objects and prevents D from accessing more chared objects owned by A.

6.2.5 Determining the Previous Context

When an applet calls JCSystem, get Pravious/ContextAID, the JCRE shall return the instance AID of the applet mature active at the time of the last context switch.

6.2.5.1 The JCRE Context

The JCRB context does not have an AID. If an applet calls the gat Provious Context at 0 method when the applet context was entered directly from the JCRE exitest, this method telumn my 1.

If the applet calls on the revious context at D from a method that may be accessed either from within the applet for when excessed via a starcable interface from an external applet, it shall clack for not 1 return before postoruing caller AID authentication.

Inva 111 Card 114 Runtinue Environneent (ICRE) 2.1 Specification

Shareable Interface Details

Javacard. Francenork. Shareable. This Shareable interface is similar in concept to the Remote luterface used by the RMI facility, in which calls to the interface methods take place across a localiformote bumplary. a ibercable luce these is unuply one that extends (either directly or indirectly) the toggibug interface

6.2.6.1 The Java Card Shareable Interface

fater faces extending the Share-abb e lagging futerface have this special property; calls to the laterface are face place across law Card's applet farwall boundary via a centeral switch.

The Shareable interface serves to identify all shared objects. Any object that needs to be shared dirough the applet fitewall shall dirocity or ludicatly implement this interface. Only those wethout specified in a shareable interface are available through the firewall.

Implementation clauses can implement any number of shareable interfaces and can eatend other starteable inpleuxatation classes.

Like any lava platform interface, a sharophe interface simply defines a set of service motiods. A service provider class declares that h "implements" the shareble interface and grovides implementations for each of the service methods of the interface. A service client class accesses the zervice by obtaining an object refaceone, castlage is to the distribute for the processor, and invoking the ervice methods of the

The strartable lucar faces within the Java Card technology whall have the following properties:

- ewitch occurs to the cornext of the object's When a mushed in a startable interface is invoked, a context
- When the method exits, the context of the tallor is restored.
- Exception landing is enlatered to that the zarreally active context is correctly restored during the stack Rant survinding that occurs as an exception is thrown.

Obtaining Shareable Interface Objects 6.2.7

Inter-apples communication is accomplished when a client applet invakes a alarcable interface method of a SIO belonging to a axis for the client applet to obtain the SIO from the second in the SIO from the client applet. In order for this to work, there auant to a way for the client applet to obtain the SIO from the second in the first place. The Applet is class and the UCSystem class provide methods to enable a client to request serviors from the Kriver.

6.2.7.1 The Melhod Applet, getShareable InterfaceObject

This method is implemented by the server applet instance. It shall be called by the ACNE to medius between a client applet that express to use an object belonging to another applet, and the server applet that makes its objects available for sharing.

The default between shall return until, which indicates that an applet does not participate in inter-applic communication.

A server applet that is introded to be invoked from another applet needs to override this inclined. This method should enabline the ci i entail by the ciperated AIDs, the usebod action of the expected AIDs, the invehod alread erection will. Smilarly, if the parameter is not recognized or lift is not showed for the

5 Copyright @ December 14, 1988 Sun Microsystems, Inc.

JAVA TH Card 144 Runtime Environment (ICRE) 2.1 Specification

ot tentato, then the method also should team outh. Ottservise, the applet should return an SIO of the sharebbe interface type that the client has requested.

The erver applet mood not respond with the same SIO to all clients. The erver can support multiple types of shared interfaces for different purposes and use calcental and parameter to determine which kind of SIO to testant to the clients.

6.2.7.2 The Method JCSystem, getAppletShareableInterfaceObject

The JCByet em class exculains the method get App Let Shar eabl of nt or faceObject, which is invoked by a cleant applet to communicate with a server applet.

The JCRE shall implement this method to behave as follows:

- I. The JCRE searthes its instemal applet table for one with serverasto. If not found, mill is returned.
- The ICRB invokes this supilet's got there and state or lace Confect method, passing the citeatall of the caller and the parrameter.
- A contait writch occurs to the server applet, and its implementation of oet Shareabiein Lor faceObject, proceeds as described in the previous action. The sarver applet rehums a SIO (or nail).
- gethopsotsharesbashetner faceobsoct returns the same SIO (or null) to its callen

Por exhinced excurity, the implementation shall make it impassible for the client to tell which of the fellowing, conditions exuced a nall value to be returned:

- The perverain was not found.

- The server applet does not periodiste in infor-applet commanication.
 The server applet does not receipable the c 11 entatio or the parameter.
 The server applet won't communicate with this client.
 The server applet won't communicate with this client as specified by the parameter.

Java 111 Card 721 Runtine Environment (ICRE) 2.1 Specification

7. Transactions and Atomicity

A transaction is a logical set of updates of peristant data. For example, transfering some entown of moving from one account to modes its a bank bag transaction. It is superfaul for transactions to be adverted either all of the data (ledds are updated, or note are. The Life Iz provides orbital supports for studine, transactional, as the case is extended to its original or transaction state is the teamsaction does not complete mometly. This in exchantism protects against notes are the superface in the original or a transaction, and against program errors that might cause data corruption should all steps of a transaction not complete normally.

7.1 Atomicity

Atonicity definet itow the cord loadles the centents of pervision stonge after a stop, failure, or falst exocption doring an update of a single object or class field or areay ocongoneon. If power is loss during the update, the appled developes stall be able to rely on what the field or stray component contains when power is restored.

The Java Card platform growness that any update to a single pendaton object or class field will be atomic. In addition, the Java Card platform provides aimje compouent level atomicity for periatent arrays. That is, if the smart card loss power during the update of a data element (field in an object/class or component of an array) that shall be preserved across CAO sessions, that date element will be restored to its practices whim.

Some inclinds also gustavice monicity for block updates of multiple data chanonis. For example, the tronicity of the Ut.11. are rayboeyr method guarantees that either all bytes are extrectly copied or class the destination seray is restored to its previous byte values.

An applet might not require atombility for anay updater. The DE it is are ay Cogystonas coulded is provided for this purpose. It does not use the transaction could be feet by the collect with a transaction in progress.

7.2 Transactions

An appier night need to atswitchly updue teveral different fields et urny components in several different objects. Either all updutes take place conocity and ecuraitently, or else all fieldu'excupentats are restored to their previous values.

The Javs Card platform supports a transactional model in which an applet on designale the beginning of an atomic set of indiance with a call to the UCByat en. boy Intrenance ton motion. Each object update after this

Copyight @ Desember 14, 1988 Sun Microsystams, Inc. 7-1

Jaya 111 Card 111 Runting Environment (ICRE) 2. I Specification

point is conditionally updated. The field on array component appears to be updated—seading the field array component back yields its fates conditional value—but the update is not yet committed.

When the appler calls acsysten, consider annuaction, all conditional updates are conunited to parsitarity storage. If power is test or if some other system fallant occurs prior to the completion of a Chypten. Constitutionally updated fields or array compounts are restored to their previous values. If the applet encounters an internal problem or decides to cancel the transaction, it can programmatically under conditional updates by calling active an about a some conditional updates by calling active and occurs of concepts on.

3 Transaction Duration

A bunnation pluays ords when the JCRE regains programmatic exated upon return free: the applied's act oct. deserted, process or tested it inclinds. This is the whether a transction ends normally, with an applied's call to examite the anacet for, or with an aborition of the transaction (either programmatically by the applied, or by default by the JCRE). For more details on transaction abortion, refer to paragraph 7.6.

Transaction chanters to the life of a transaction between the call to a CSystem, beging ransaction, and eithor a call to committ commaction or an aborison of the transaction.

4 Nested Transactions

The nodel currenty assumes that nested translations are act possible. There can be only one transaction in progress at a time, if 1629 of ea. best navenues from it called while a transaction is already in progress, then a transact toatheopy.

The JCSystem, transact Loodepth inclind in provided to allow you to deternible if a transmitor is in progress.

7.5 Tear or Reset Transaction Failure

Ifpower is lest (teat) or the card is read or some other system faiture occurs while a transdition is in progress, then the ICRE shall restore to their previous values all fields and anay comparents conditionally updated find the previous call to ICRE steam, begin Transact Ion. This action is parformed susmaistally by the JCRE when it ceintializes the card silve recovering from the power loss, reset, or faiture. The JCRE determines which of those objects (if any) were conditionally updated, and returns then.

Note—Object space used by instances cereated during the transaction that failed due to power loss or card reset can be recovered by the ICRE.

7-2 Copyright @ December 14, 1998 Sun Microsystems, Inc.

01/22/99

7.6 Aborting a Transaction

Transactions can be aborted either by an applet or by the JCRB.

7.6.1 Programmatic Abortion

If an applet cocounters an internal grobitern or decides to conset the upmassition, it can programmatically undo conditional updates by calling JCS/yeares about Transact ton. If this method is called, all conditionally updated fields and sersy compounts since the previous call to JCS/yet on .b oq Intransact ton ser calined to their previous values, and the JCS/yet on .t can sect I can sect of one to the line.

7.6.2 Abortion by the JCRB

If an applet return from the select, despice t, process, or install nythods with a transcion is progress, the ICRE summatically about the transaction. If a return from my of select, despelect, process or install nethods occurs with a transaction in progress, the ICRE acts as if an exception was fluoun.

7.6.3 Cleanup Responsibilities of the JCRE

Object intances created thering the transaction that is being aborted can be deleted only if all references to these objects can be located and converted into null 1. The ICRE sludi crame that references to objects created than ing the aborted transaction are equivalent to a null 1 reference.

7 Transient Objects

Orly updates to persistant objects participate in the transaction. Updates to transiont objects are news undone, regardies of whether even they were "hisfule a transaction."

.8 Commit Capacity

Since platicam resources are invited, the number of bytes of conditionally updated thus that can be accumulated during a transparion is limited. The Jaw Cred technology providet untilteds to determine they much remunit engagely is available on the implementation. The content expectity represents an upper bound on the number of conditional byte updates available. The notal number of conditional byte updates available. The notal number of conditional byte updates available truy be tower due to management overthest.

An exception is thrown if the casmit especity is exceeded draing a transaction.

Jara 14 Card 14 Runtine Environment (ICRE) 2.1 Specification

API Topics ∞

The topics in this chapter complement the requirements specified in the Jana Carl 2.1 API Druft 2. Specification. The first topic is the Java Card IVO functionality, which is implemented entirely in the APOs class. The second topic is the API supporting Java Card accurity and cryptography. The actages on class encapulates the API version level.

Transactions within the API

Lisbers specifically called out in the Javy Card 1.1 API Goacification, the implementation of the API classes stall not initiate or other wise alsor the state of a transaction If one is it progress.

Resource Use within the API

Unless specifically called out in the Jone Cart 1.1 API Specification, the implementation shall support the invocation of API tastates inclined, even when the owner of the object instance is not the curronity selected applier, in other words, unless specifically called out, the implementation shall not use resources such as remained objects of CLEAR_ON_DESELECT type.

Exceptions thrown by API classes

All exception objects thrown by the API implementation shall be temponary KPBE Enry Polen Objects. Temponary JCRE Entry Point (Björls cannot be stored in clars variables, instance variables or array components (Sev 6.2.1)

The APDU Class — ∞

The APDU class encapsulates access to the ISO 7816.4 hased MO serves the cut d serial line. The APDU Class in designed to be independent of the underlying I/O vanisport protected.

The JCRE may support T=0 or T=1 transport protocols or both.

T=0 specifics for outgoing data transfers 8.1.

For occupatability with legacy CADAeminals that do not support block thained mechanisms the APOU Class sellows mode refection via the set Coutgo LingHoChe In ing inclined.

<u>.</u> Capyright @ December 14, 1998 Sun Microsystems, Inc.

Java Ta Card Ta Runtine Environment (JCRE) 2.1 Specification

01/22/99

8.1.1.1 Constrained transfers with no chaining

When the no chaining mode of output transfer is requested by the applet by eatling the setOutgoingMochaining method, the following prolocol sequence shall be followed.

Note —when the no chaining mode is used, calls to the walt Ext emplon method shell throw an Appulaceout on with reason code ILLEGAL, USB.

FRI 10:34 FAX 650 854 0875

Le = CAD expected laught.

Lr = Appict response length set via set Outgo ingliength mediad.

<INS> = the protocol byte equal to the incoming beader IMS byte, which indicates that all data bytes will be transferred next.

«-INS» = the protocol byte that is the complement of the incoming header INS byte, which indicates should data byte being transferred next.

<SWI, SW2> = the response status bytes as in 1807816-4.

ISO 7816-4 CASE 2

ا ا

). The card pends Le bytes of output data using the standard T=0 <1NS> or <-1NS> provedure

2. The card smids <SWI SWD completion teats on completion of the Applet. process

1. The card sends 40x61, Les completion status bytes

2. The CAD sends GET RESPONSE exempsed with Le = Lr.

). The card sends Lr byses of onignat data using the wandard T=0 < $|MS>\propto \kappa$ < |MS> procedure byse mechanism.

4. The card sends $<\!8W1,\!8W2\!>$ completion status to completion of the App Let . process method.

<u>r, te</u>

1. The card sends Le bytes of outpet date wing the standard T=0 < INS> or <-INS> procedure byte mechanism.

2. The card sends <0x61,(L.-La)> camplection status bytes

3. The CAD seeds GET RESPONSE command with new Le <= Lr.

4. The cud world (usw) Le byter of supm data using the usandard T=O <IND or <-IND procedure byte modulation.

Copyright @ December 14, 1998 Sun Microsystems, Inc. **6.**2

lava 14 Card 14 Rundine Environnent (ICRE) 2.1 Specification

Repeat steps 2-4 as necessary to send the remaining output data bytes (Lt) as required.

6. The eard sends <SW1,SW2> completion status en completien of the App Lot . process method.

ISO 7816-4 CASE 4

In ('see 4, Le is determined after the following initial enchange:

1. The eard sends <0x61,Lr seatus bytes

2. The CAD sends GET RESPONSE command with Lo <= Ls.

The rest of the protocul requence is idunieral to CASE 2 described above.

If the applied abouts ready and sernids less than Le bytes, serious may be sent insuced to fill out the bangth of the beaster expected by the CAD.

8.1.1.2 Regular Output transfers

When the no chaining mode of output transfer is not requested by the applet (that is, the seatOutgod not method is used), the following protocol sequence shall be followed:

Any ISO-7816-3M compliant T=O protocal transfer sequence any be used.

More — The wast Ext ension inclind may be invoked by the applet between successive rails to sendiby test or sendiby testions methods. The wast tents ion method slad request an additional work maring time (ISO 1816.3) value the Carlo procedure byte.

8.1.1.3 Additional T=0 requirements

At any fane, when the T=D output transfer protocol is in use, and the APDU class is availing a CET RESPONSE command it can be CAD in readicts to a response status of cOx61, xn> from the card, if the CAD sends in a different commund, the acadityte as or the sendibyte estioning methods shall throw an APDUExcept ion with resean code NQ_TO_CEWRESPONSE.

Calls to sendby ton or sendby tectoog mellock from this point on skall result in an APDOExcept ton mith reason code JL-BOAN. USE. If at LEOBERCEPT ton is thrown by the applet sile the trQ_TO_GBFRES PONSE exception has been thronn, the JCRE shall discust the tesponse status in its reason code. The JCRE thall resunt APPIU processing with the newly received command and returne APDU disputching.

8.1.2 T=1 specifics for outgoing data transfers

8.1.2.1 Constrained transfers with no chaining

When the no chaining made of output transfer is requested by the applet by calling the set Out-go Angatoc stad be followed:

Notation

Le = CAD expected length.

 $\mathbf{L}=\mathsf{Applet}$ response length set via set Outgo Lng Leng Lh method

Capyright © December 14, 1968 Sun Marceystems, Inc. 8-3

Java TM Card TM Runtime Environment (JCRE) 2.1 Specification

The mengory profited acquence shall not use block chaining. Specifically, the bit this (more data bit) shall not be set in the PCB of the t-blocks during the transfers (ISO 7816-3). In other words, the entire origoing data (Labyers) shall be transferred in one t-block.

(If the applies about seafy and sends less than Le bytes, zeros shall be sent instead to fill out the resusiaing knyth of the blook.)

Nobe — When the no chaining mode it used, calls to the wait Extension nethod vivalithm on an Artutakeoption with resea code 1 LLEGAL_USE.

8.1.2.2 Regular Output transfers

When the no chaining mode of autout vauster is not requested by the styden i.e. the sectout going arethod is used, the fellowing protocol sequence shall be fellowed:

Any ISO-7816-3/4 compliant T=1 protocol transfer sequence may be used.

Note—The wat Leartens I on method may be invoked by the applet between successive cults to send Bytes or send Bytest command with WTX (squest of INF unit, which is expiratent to a request of I additional work varieting time in T=O mode. (See ISO) 1816-1).

2 The security and crypto packages

The got I not ancome method in the following classes return an implementatives instance in the contest of the calling applet of the requested algorithms:

javacard.security.NessageDigest

javacard.security.Signature

javacard.security,RandomData

Javacarda, crypto.Cipher.

An implementation of the ICRE may implement 0 or more of the algorithms fixind in the API. When an algorithm that is not implemented is requested this method shall throw a Crypt of accept I on with reason code at 0.5 such _ALZORITHER.

Implementations of the above classes shall entend the corresponding base class and implement all the abuncal methods. All data allocation associated with the implementation instance shall be performed at the time of instance construction to ensure that any tack of required resources can be flagged early during the installation the applet.

Similarly, the but Lidkey method of the Invacord, security, keyBus Ider class idums on Implementation instance of the requested Key type. The ICRE may implement the more types of keys. When a key type that it not implemented is requested, the method shall throw a Cryptockneept son with reason code no. Such Incontrick.

Capyright @ December 14, 1938 Sun Microsysiems, Inc. 6-5

Java M Card M Runline Environment (JCRE) 2.1 Specification

Implementations of key types that implement the associated interface. All data allocation essociated with the key implementation is enume that any fact of tentanes ownstruction to enume that any fact of experient resources can be flagged early dering the intallation of the applet.

8.3 JCSystem Class

In Jave Card 2.1, the getver's ton method draft return (sixet) 640201.

9. Virtual Machine Topics

Java 1M Card To Ruptime Environment (JCRE) 2.1 Specification

The topics in this chapter detail virtual mechine specifica.

9.1 Resource Failures

A lark of resources condition (auch as heap space) which is recoverable shall result in a SystemExcept ton with reason code 100_RESOURCE. The followy included in aCBystem used to create transient arrays throw a systemExcept ton with reason code 110_TRANSTEAT_SPACE to indicate lade of translerst space.

All other (non-recoverable) virtual machine errors such as stack overflow chall result to a virtual machine error. These conditions shall cause the virtual machine to balt. When such a non-recoverable virtual machine error occurs, an implementation can optionally requise the eard to be manted or blocked from further asso. Copyright @ December 14, 1898 Sun Microsystems, Inc. B-1

Java Tu Card TH Runtine Environment (JCRE) 2.1 Specification

10. Applet Installer

Applet intalitation on smart cards using lava Card technology is a complex topic. The Java Card API 2.1 is included to give JCRE implementarians as much freedom as possible in their implementations. However, avent basic commen specifications are required in order to altow Java Card applots to be installed without knowing the implementation details of a particular installer.

This specification defines the concept of an Instalber and specifies minimal installation requirements in order to achieve interoperability across a wide tenge of presuble hatalter implementations.

The Applet lossiller is an optional past of the ICRE 2.1 Specification. Thus is, an implementation of the ICRE does not necessarily need to include a past-sissuance tradition. However, if singularizated, the installar is required to support the behavior specified in section 9.1.

10.1 The Installer

The mechanisms necessary to lastell an applet on snewt eards using lava Card technology are embodied in an on-

To the CAD the fushaler appears to be an applie, in has an AID, and it bocomes the currently actored applied when this AID is successfully processed by a SELECT commissed. Once adhered, the Installer betases in much the came way as any other applet:

- It receives all APDUs just 18to any other selected applied.
- its design specification prescribes the various kinds and formats of APDUs that it expects to receive along with the servanics of these commands under various precouditions
 - It processes and responds to all APDMs that it receives, lucuree: APDMs are responded to with an error
 - condition of some kind
- When poolings applied in selected (or when the card is read or when power in removed from the card), the Invaller becomes desclected and remains impended until the next linue that it is SELECTed.

10.1.1 Installer Implementation

The fusivities need not be implemented as an appet on the card. The requiernment is only that the hastaller functionally be SELECTABE. The covaliary to this requiernment is that tensuler component shall net be able to be invoked when a more-installer applet is selected nor when no applet is selected.

흗 Copyright @ December 14, 1998 Sun Misrasystams, Inc.

Java 14 Card 114 Runtime Environment (ICRE) 2.1 Specification

Obviously, a ICRE implementer could choose to implement the Installer as an applet. If so, then the Installer might be coded to extend the Appl et class and respond to invocations of the select, processe, and deselect methods.

But a ACRE implementer could also implement the Institute in other ways, as long as it growder the SELECTABLE beflavior to the cutnide world. In this case, the JCRE implementer has the freedom to provide some other mechanism by which APDUs are delivered to the Installer code module.

10.1.2 Installer AID

Decause the Installar is SELECTable, it shall have an AID. JCRE implementers and free to choose their own AID by which their Installar is selected. Multiple installars may be implemented.

10.1.3 Installer APDUs

The lana Card API 2.1 does not specify any APDUs for the Intraller. JCRE implementers are entirely free to choose their own APDU commands to direct their Installer in its work. The model is that the Installer on the card is driven by an installation program remining on the CAD. In order for installation to succeed, this CAD installation programs shall be able to:

- Recognize the card.
- SELECT the limitality on the card.
- Drive the installation process by senting the appropriate APOUs to the card installer. These APDUs will
 - contain:

 - Authentication information, to ensure that the installation is sufficience.
 The applet code to be loaded into the card's memory.
 Linkage information to fink the applet onde with code already on the card.
 Instance initialization parameter data to be sent to the applet's installation.

The Java Card AFI 2.1 does not specify the details of the CAD instillation program nor the APDUs parced between it and die lustaller.

Installer Behavior 10.1.4

ICRE limplementers shall also define other behaviors of their installer, inchiding:

- Whether or not installation can be sharted and how this is done.
- What happens if an exception, react, or power fail occus during installation. What happens if another applet is selected before the Installer is fortabled with its work.

The ICRE shall guarantee that an applict will not be deemed successfully installed if:

the applet's finata it inschool flyous an exception before successful return from the Appliat, register unched. (Refer to paragraph 9.2.)

Capyright @ December 14, 1988 Sun Nizrasystems, Inc. 200

10.1.5 Installer Privileges

Atthough an installer may be implemented as an apple, an installer with typically require access to features that are not available to "other applan. For example, depending ou the ICRE implementer's implementation, the Installer will seed to:

Read and write directly to mentory, bypassing the abject system and for similard security. Access abject owned by other applets or by the RCRE. Invoke non-cutry point nethods of the JCRE.

FRI 10:36 FAX 650 854 0875

01/22/99

- Be able to invoke the install method of a newly installed apples.

Agair, it is up to each FCRE implementer to determine the installer implementation and supply such features the their ICRE implementers are also responsible for the accurity of such features, so that dicy are not available to membal applicts.

10.2 The Newly Installed Applet

There is a single interface between the (madifer and the applet that it being installed. After the loatsitic has correctly prepared the applet for execution (performed steps such as loading and ituking), the Installer shall invoke the applet's tract all inveltad. This method is defined in the Applet class.

The precise machanism by which an applet's install method is invoked from the tratalier is a JCRE implementation draft. However, there shall be a contral switch so that any context-related programment by the Linetall inchind (such as corating prev objects) are done in the context of the new applit and not in the context of the Inaialter. The Installer shall also ensure that zeray objects created thring applie center initialization («climit») unchoods are also owneed by the context of tho new applie.

The invaluation of an appliet is decored compliate if all stops are exampleted without failure or an example being thrown, up to and including moversalal retions from executing the Appliet , read at or include. At that point, the installed applier will be selectable.

The manimum size of the parameter data is 32 bytes. And for arcunity reasons, the barray parameter is zeroed soften the setum fosts as the APDJ buffer is recood on setum fosts an applic's process method.)

10.2.1 Installation Parameters

Other than the maximum size of 32 bytes, the Jawa Card API 2.1 does not apoxify anything about the excitenta of the installation garanation byte array segment. This is fully defined by the applied designes and can be in any former desired. In addition, these firstallation parameters are intended to be opseque to the fustallar.

ACRE implementors aloueld design store installers so that is to possible for an installation program runding in a CAD to specify an arbitrary byte erray to be delivered to the finitalier. The Installer simply forwards this byte array to the target applet's traceas unretted in the barrery parameter. A typical laphementalion night define a JCRE implementer proprietary APDU command that has the economies "call the applet" and tall intollod passing the corrects of the accompanying byte array." Jaya Tu Card Tu Runtin's Environment (JCRE) 2.1 Specification

Glossary

AID is an acconym for Application I Dentifer as defined in 150 7816-5

APDU is an accompto for Application Protocol Date Unit as defined in ISO 7816-4.

API is an acrown for Application Programming har face. The API defines calling conventions by which an application program soccess the operating system and other services.

Applet within the centest of this document wissans a layar Card Applet, which is the basic smit of safection, contest, functionality, and security in Java Card technology.

Apples deretaper refers to a paran creating a Java Card applet using the Java Curd tachmology specifications.

Applet fremall is tite mechanism in the Jawa Card technology by which the VM prewait an applet from making unauthorized accesses to objects owared by when applet contexts or the JCRE montext, and reports or otherwise addresses the violation.

Atomic operation is an operation that either complotes in its entirely (if the operation secceeds) or no part of the operation completes at all (if the operation fails). Atomicity setters to whether a particular operation is atomic or tool and is nocessary for proper data recovery in cases in which power is last or the eard is was a peolecity removed from the CAD.

ATR is an accompan for Ansewer to Reson. An ATR is a airing of bytes tent by the lass Card after a resel

CAD is an eccurym for Card Accorplance Device. The CAD is the device in which the card is inserted.

Cast is the explicit curversion from one data type to another.

eACK is the test suite to verify the compliance of the implementation of the Iava Card Tochnology specifications. The eACK uses the IavaFest tool to much test suite.

Class is the prototype for an object in an object-oriented language. A class may also be considered a set of objects this three a consumen structure and behavior. The structure of a class is determined by the class variables that requested the state of an object of that class and the behavior is given by a set of methods associated with the class.

Classes are retained in a class librarchy. One classes may be a specialization (a subclass) of another (its superdass), it may have reference to oliter classes, and it may use other classes in a clima-server relationalip.

Content (See Applet execution content.)

Currently active content. The ICRE leeps track of the currently active have Card applet content. When a virtual method is threefed on an object, and a centent switch is required and permitted, the currently active

omitent is changed to correspond to the applet content that owns the object. When that medical returns, the previous centent is restored. Invocations of static methods have no effect on the currouly active content. The currouly active content and thaning lature of an object to object to determine if access to an object to permissible,

Currently asketed applet. The ICRR house track of the currently selected Java Card applet. Upon receiving a SELECT command with filis applet 's AID, die JCRE nakes this applet the currently relected applet. The JCRE search sall APDU commands to the currently selected applet.

BBFROM is an acronym for Electrically Brassble, Programmebe Read Only Menory.

Firewall (see Applet Firewall).

Framework is the ast of classes that implement the API. This includes core and extension packages. Responsibilities include dispatching of APDUs, appet selection, intraging atomizity, and installing applets. Carbage reliection is the proots by which dynamically affected streage is autounitally reclaimed during the execution of a program. fastance variables, also kuows as fields, egoresten a posison of an object's internal state. Each object has lu own set of loatance variables. Objects of the same class will have the same instance variables, but each objec can lave different values. Invantation, in object-oriented programming, mema to produce a particular object from its cluss templue. This involver allocation of a data structure with the types apocified by the template, and initialization of sinusore variables with either default values or those provided by the class's contractor function.

JAR is an aeronym for Java Aerbive. JAR is a platform-independent tile format diat combines many files into vote. Java Card Runtime Bartronment (ICRB) consists of the lava Card Virtual Mactime, the framework, and the associated native methods.

JC21Rt is an accompan for the lave Card 2.1 Reference Implementation.

JCRE implementer reference presencreating a vendor-specific implementation using the lava Card API.

JCVAI is an exxayın for the Java Card Virusi Mesbine. The JCVAI is the fixundation of the OF card architecture. The JCVAI executes byte code and manages chases and objects. It enforces separation between applications (thewalls) and enables secure data shoring.

JDK is an acronym for Java Devetopment Kir. The JDK is a Sun Mizronystem, Inc. probact that provides the conviconment required for programming in Java. The JDK is available for a variety of platforms, but modicionally the Society that Society and Microsoft Windows."

Method is the name given to a procedure or rontine, associated with one or more clarses, in object-oriented languages.

Namespace is a set of tumes in which all tunces are tanigne.

Object-Oriented is a programming neckodology based en the econogi of an object, which is a data almetu encapsulated with a set of conisines, culled merhods, which expense on the class. Objects, in object-criented programming, are unique instances of a data structure defined according to the template provided by its class. Each object has its own values for the variables belanging to its class and can respond to the insuages (methods) defined by its class.

Java 124 Card 124 Runline Environment (JCRB) 2.1 Specification

Parkage is a namespace within the Pava programming language and can tave classes and interfaces. A package is the amilies unit within the Java programming language.

Persistent object Persistent objects and their values passis from one CAD session to the seas, indefinitely.

Objects are persistent by the fault. Persistent object withte are updated atomically using transactions. The term perefatent does not neven three is an object-oriented dustwase on the card or that objects are serialized/describilized, just that the Objects are not less the serialized/describilized, just that the Objects are not less the serialized dustwase.

Shareable laterface Defines a set of that of sites face mediods. These luter hoe methods can be invoked from one applet context when the object implementing them is owned by another applet centext.

Sharrabhe talerface object (SIO) An object that implements the starcable interface.

Transaction is an atomic operation in which the developer defines the extent of the operation by indicating in the program code the beginning and end of the transaction.

Translent abject. The values of translent objects do not praising boin one CAD session to the next, and are reset to a default state at specified intownly. Updates to the values of translets objects are not atomic and are not an affected by transactions.

f RE D2 14DEC98:READ-ME-JCRE21-DE

Ext

Date: 16 December 1998

Dear Java Card Licensee,

JCRE21-DF2-14DEC98.zip contains a second draft of the Java Card 2.1 Runtime Environment specification, dated December 14, 1998, for Licensee review and comment. We have worked to incorporate and clarify the document based upon the review feedback we've received to date.

Complete contents of the zip archive are as follows:

READ-ME-JCRE21-DF2.txt JCRE21-DF2.pdf - This READ ME text file

- "Java Card Runtime Environment (JCRE)

2.1 Specification" in PDF format

JCRE21-DF2-changebar.pdf - The revised document with change bars from the previous version for ease

of review.

OI LEVI

Summary of changes:

- 1. This is now a draft 2 release and will be published on the public web site shortly.
- 2. New description of temporary JCRE Entry Point Objects has been introduced for purposes of restricting unauthorized access. Firewall chapter 6.2.1.
- 3. Global arrays now have added security related restrictions similar to temporary JCRE Entry Point objects. Firewall chapter 6.2.2.
- 4. Detailed descriptions of the bytecodes with respect to storing restrictions for temporary JCRE Entry Point Objects and Global arrays added. Chapter 6.2.8.
- 5. General statement about JCRE owned exception objects added in chapter 8.
- 6. Corrected description of Virtual machine resource failures in transient factory methods. Chapter 9.1.

The "Java Card Runtime Environment 2.1 Specification" specifies the minimum behavior and runtime environment for a complete Java Card 2.1 implementation, as referred to by the Java Card API 2.1 and Java Card 2.1 Virtual Machine Specification documents. This specification is required to ensure compatible operation of Java Card applets. The purpose of this specification document is to bring all the JCRE elements together in a concise manner as part of the Java Card 2.1 specification suite.

Please send review comments to <javaoem-javacard@sun.com> or to my address as below. On behalf of the Java Card team, I look forward to hearing from you.

Best, Godfrey DiGiorgi
